# A SOLUTION TO SHEIL-SMALL'S HARMONIC MAPPING PROBLEM FOR JORDAN POLYGONS

DAOUD BSHOUTY, ERIK LUNDBERG, AND ALLEN WEITSMAN

Abstract. The problem of mapping the interior of a Jordan polygon univalently by the Poisson integral of a step function was posed by T. Sheil-Small (1989). We describe a simple solution using "ear clipping" from computational geometry.

## 1. Introduction

In the subject of planar harmonic mappings, the mappings which arise as Poisson integrals of step functions, especially those which are univalent, play a prominent role (cf. [4, pp.59-75]). When the mapping is univalent, the image is a domain bounded by a Jordan polygon with its vertices at the steps of the boundary function.

Mappings of this type also appear when conformally parametrizing minimal graphs known as Jenkins-Serrin surfaces [5]. These are minimal graphs which take values $\pm\infty$ over the sides of a domain bounded by a Jordan polygon, and if the parameter space is taken to be the unit disk $U$, then the first two coordinate functions of the parametrization give a univalent harmonic mapping which is given by the Poisson integral of a step function [2].

In 1989, T. Sheil-Small [9] made a study of the mapping properties of Poisson integrals of step functions and posed the following problem.

**The mapping problem**. *Given a domain $D$ bounded by a Jordan polygon, does there exist a univalent harmonic mapping $f$, which is the Poisson integral of a step function, such that $f(U) = D$?*

There is a classical univalence criterion for harmonic mappings of $U$ onto a convex domain. The problem stated by T. Radó in 1926 [8] and solved by H. Kneser [6] the same year, shows that for any homeomorphism of the unit circle $\partial U$ onto the boundary $\partial D$ of a convex domain $D$, the harmonic extension maps $U$ univalently onto $D$. Later G. Choquet [3] gave another proof which allowed the boundary function to be constant on arcs, and even to have jump discontinuities. Thus, by Choquet's theorem, the mapping problem has a positive solution when the polygon is convex.

This mapping problem has also been repeated in the book [10, p. 402] and more recently in the book [1, p. 314]). Also it was conjectured in [9] that there would be polygons for which there is no such mapping.

In this paper we shall describe an algorithm which leads to a positive solution to the mapping problem.

**Theorem 1.1.** *Given any Jordan polygon* $\Pi$ *bounding a domain* $D$*, there exists a step function* $f(e^{it})$ *on* $\partial U$ *whose harmonic extension gives a univalent harmonic mapping of* $U$ *onto* $D$*.*

In order to state the problem precisely, consider the polygon $\Pi = [c_1, c_2, .., c_n, c_1]$ as a positively oriented Jordan curve with distinct vertices $c_k$ bounding a domain $D$. For a sequence of intervals $0 = t_0 < t_1 < .. < t_n = t_0 + 2\pi$, consider the Poisson integral $f(z)$ of the (complex) step function (also denoted by $f$)

$$f(e^{it}) = c_k \quad (t_{k-1} < t < t_k). \tag{1.1}$$

The problem then comes down to showing that there is a choice of $t_0, t_1, ....., t_n$ for which the Poisson extension is univalent.

We prove this theorem in Section 2. In Section 3, we describe an estimate for harmonic measure in a half-plane which can be useful in determining the univalence across the sides of a polygon as it arises as the image of the Poisson integral of a step function.

## 2. A solution to the mapping problem (proof of Theorem 1.1)

We follow the notation in [9].

With $f(z) = h(z) + \overline{g(z)}$ represented by analytic functions $h$ and $g$, it is enough to show, by Theorem 5 in [9], that the zeros of

$$h'(z) = \sum_{k=1}^{n} \frac{\alpha_k}{z - \zeta_k}$$

are outside $U$ the unit disk, where $\alpha_k = \frac{1}{2\pi i}(c_k - c_{k+1})$ for $k < n$, and $\alpha_n = \frac{1}{2\pi i}(c_n - c_1)$, and $\zeta_k = e^{it_k}$, for $k = 1, .., n$.

We give a proof by induction on the number of vertices.

**Induction statement:** Given any Jordan $n$-gon, there exists a sequence of intervals such that the zeros of $h'(z)$ are in $\mathbb{C} \setminus \overline{U}$.

The "base case" $n = 3$ is a triangle and the statement follows from the Rado-Kneser-Choquet Theorem.

Inductive step: Suppose the Induction Statement is true up to some $n$. Consider a Jordan $n+1$-gon, $\Pi = [c_1, c_2, .., c_{n+1}, c_1]$. We follow the triangulation algorithm known as "ear clipping". Namely, find a vertex of $\Pi$, without loss of generality assume the vertex is $c_{n+1}$, such that removing it results in a Jordan polygon with $n$ vertices. Such a vertex is called an "ear" in computational geometry, and it is well-known that every Jordan polygon has at least two ears [7].

**Lemma A.**(The "two ears" theorem) *Any Jordan polygon has at least two "ears".*

Consider the $n$-gon $\Pi' = [c_1, c_2, .., c_n, c_1]$. By the induction statement, there is a choice of intervals

$$0 = t_0 < t_1 < .. < t_n = t_0 + 2\pi$$

so that the Poisson integral of the corresponding step function $f(z)$ is univalent, and the zeros of $h'(z)$ are outside the closed unit disk $\overline{U}$.

We construct a map $f_\varepsilon(z)$ to $\Pi$ by making a new choice of intervals

$$0 = \tau_0 < \tau_1 < .. < \tau_n < \tau_{n+1} = \tau_0 + 2\pi.$$

Namely, we take $\tau_k = t_k$ for $k = 0, 1, .., n-1$ and $\tau_n = 2\pi - \varepsilon$. Then $f_\varepsilon(z)$ is taken to be the Poisson integral of the step function

$$f_\varepsilon(e^{it}) = c_k \quad (\tau_{k-1} < t < \tau_k).$$

In comparison with the choice of intervals used for the map $f(z)$, this slightly alters the interval corresponding to $c_n$ and introduces a new interval $(\tau_n, \tau_{n+1})$ of size $\varepsilon$ corresponding to the ear $c_{n+1}$ (see Figure 1

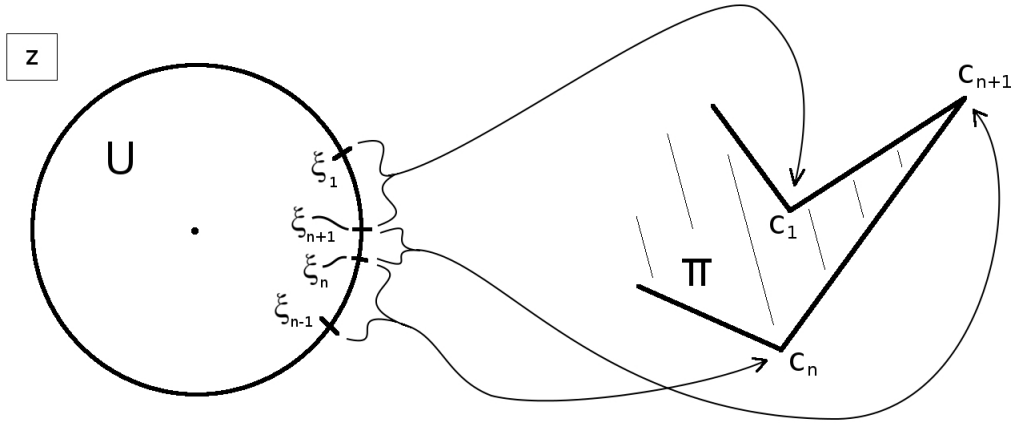

FIGURE 1. Illustration of the map $f_\varepsilon$ in the vicinity of the ear $c_{n+1}$.

With these choices and using the notation $\beta_k = \dfrac{1}{2\pi i}(c_k - c_{k+1})$ for $k = 1, .., n$, $\beta_{n+1} = \dfrac{1}{2\pi i}(c_{n+1} - c_1)$, and $\xi_k = e^{i\tau_k}$ for $k = 1, .., n+1$, we have

$$h'_\varepsilon(z) = \sum_{k=1}^{n+1} \frac{\beta_k}{z - \xi_k}, \tag{2.1}$$

where $h_\varepsilon(z)$ is the analytic part of $f_\varepsilon(z)$.

**Claim 1:** As $\varepsilon \to 0$, $h'_\varepsilon$ approximates $h'$ uniformly outside any neighborhood of the point $\xi_{n+1} = 1$.

To verify Claim 1, we note that the first $n-1$ terms in the sum (2.1) are the same as the first $n-1$ terms in

$$h'(z) = \sum_{k=1}^{n} \frac{\alpha_k}{z - \zeta_k}.$$

Thus, in order to prove Claim 1 we only need to check that as $\varepsilon \to 0$ the last two terms in $h'_\varepsilon$

$$\frac{\beta_n}{z - \xi_n} + \frac{\beta_{n+1}}{z - \xi_{n+1}}$$

converge uniformly to the last term in $h'$

$$\frac{\alpha_n}{z - \zeta_n} = \frac{c_n - c_1}{z - 1},$$

which follows from

$$\frac{\beta_n}{z - \xi_n} + \frac{\beta_{n+1}}{z - \xi_{n+1}} = \frac{c_n - c_{n+1}}{z - e^{-i\varepsilon}} + \frac{c_{n+1} - c_1}{z - 1}.$$

By Claim 1 and Hurwitz's theorem, $h'_\varepsilon$ has a zero near each of the zeros of $h'$. For $\varepsilon > 0$ sufficiently small, this places at least $n-2$ (counting multiplicities) of the $n-1$ zeros of $h'_\varepsilon$ outside $\overline{U}$ (not counting $\infty$ which is a zero of multiplicity two).

It remains to show that the final zero of $h'_\varepsilon$ is also outside $\overline{U}$. Estimating the location of this zero is slightly complicated by the fact that it converges to $\xi_{n+1} = 1$, the point where two poles are merging as $\varepsilon \to 0$. Thus, we use a renormalization.

Let us write $z = \varepsilon w + \xi_{n+1} = \varepsilon w + 1$, and

$$H_\varepsilon(w) := h'_\varepsilon(\varepsilon w + 1).$$

By the above, $H_\varepsilon(w)$ has $n-2$ zeros (counting multiplicities) converging to $\infty$ as $\varepsilon \to 0$. The remaining zero converges to a finite point $w = w_0$ in the right half-plane as follows from the next claim.

**Claim 2:** $H_\varepsilon(w)$ has a zero at $w = w_\varepsilon$ such that

$$w_\varepsilon \to w_0 := -\frac{c_{n+1} - c_1}{c_n - c_1} i, \quad \text{as } \varepsilon \to 0.$$

Before proving Claim 2 let us see how it establishes the result. It follows from the fact that $[c_n, c_{n+1}, c_1]$ is an *outside* corner that the argument of $\dfrac{c_{n+1} - c_1}{c_n - c_1}$ is strictly between zero and $\pi$. Thus, $-\dfrac{c_{n+1} - c_1}{c_n - c_1} i$ is in the right half-plane, and, for $\varepsilon$ sufficiently small, $w_\varepsilon$ is also in the right half-plane. This places $\varepsilon w_\varepsilon + 1$ (the remaining zero of $h'_\varepsilon$) outside of $\overline{U}$, and this completes the inductive step.

It remains to prove Claim 2.

*Proof of Claim 2.* We have

$$\varepsilon H_\varepsilon(w) = \sum_{k=1}^{n+1} \frac{\beta_k}{w + (\xi_{n+1} - \xi_k)/\varepsilon}. \tag{2.2}$$

Choose a disk $V$ centered at the point

$$w_0 := -\frac{c_{n+1} - c_1}{c_n - c_1} i$$

such that $\overline{V}$ omits each of the points $w = 0$ and $w = -i$. As $\varepsilon \to 0$, the first $n-1$ terms in (2.2) converge uniformly to zero in $V$ while the final terms

$$\frac{\beta_n}{w + (\xi_{n+1} - \xi_n)/\varepsilon} + \frac{\beta_{n+1}}{w}$$

converge uniformly to

$$\frac{\beta_n}{w + i} + \frac{\beta_{n+1}}{w}, \tag{2.3}$$

where we have used

$$\frac{\xi_{n+1} - \xi_n}{\varepsilon} = \frac{1 - e^{-i\varepsilon}}{\varepsilon} = \frac{1 - (1 - i\varepsilon + O(\varepsilon^2))}{\varepsilon} = i + O(\varepsilon).$$

This last expression (2.3) has a single zero in $V$, namely at

$$w_0 = -\frac{\beta_{n+1}}{\beta_n + \beta_{n+1}} i = -\frac{c_{n+1} - c_1}{c_n - c_1} i.$$

By Hurwitz's Theorem (2.2) has exactly one zero in $V$, and this zero converges to $w_0$.

□

## 3. The law of sines lemma

In this section, we replace the unit disk with the upper half-plane $H$, and consider the harmonic measure $\omega_I$ in $H$ of an interval $I$ on the real axis. The asymptotic behavior of $\omega_I(z)$ as $z \in H$ approaches a point on the real axis can be used to detect possible folding near an edge of the image polygon $\Pi$. Lemma 3.1 below was an initial guide for Theorem 1.1, although in the end we did not need it. However, it seems that it may be of independent interest.

Recall that for $z \in H$, the harmonic measure $\omega_I(z)$ of an interval $I \subset \mathbb{R}$ equals the angle between the two segments joining $z$ to each of the endpoints of $I$.

**Lemma 3.1** (Law of sines lemma)**.** *Suppose $x_0 < x_1 < x_2$ are points on the real axis and the intervals $[x_0, x_1]$ and $[x_1, x_2]$ have length $A$ and $B$ respectively. Suppose*

*$z \in H$ approaches $x_0$ along a segment. Let $y$ be the imaginary part of $z$, and let $\omega(z)$ denote the harmonic measure of $[x_1, x_2]$. Then,*

$$\frac{\omega(z)}{y} \to \frac{B}{A^2 + AB} \quad (as\ z \to x_0).$$

*In particular, this limit is independent of the angle of approach of $z \to x_0$.*

*Proof of Lemma.* Let $x$ be the real part of $z$ and let $A' = x_1 - x$.
By the law of sines,

$$\frac{\sin\theta}{B} = \frac{\sin\psi}{C} = \frac{y/\sqrt{y^2 + (A'+B)^2}}{\sqrt{y^2 + A'^2}},$$

where $\psi$ is the angle of the corner $[x_0, x_2, z]$, and $C$ is the length of the segment $[x_1, z]$.
Rearranging,

$$\frac{\sin\theta}{y} = \frac{B}{\sqrt{y^2 + (A'+B)^2}\sqrt{y^2 + A'^2}}.$$

Letting $z \to x_0$, we have $A' \to A$, and $y \to 0$. Thus,

$$\frac{\sin\theta}{y} \to \frac{B}{(A+B)A}.$$

Since

$$\sin\theta = \theta + O(\theta^3),$$

we have

$$\frac{\omega(z)}{y} \to \frac{B}{A^2 + AB},$$

as $z \to x_0$. □

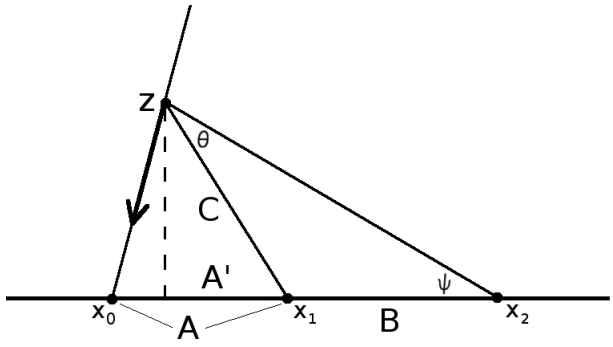

FIGURE 2. $z$ approaches $x_0$ along a fixed angle.

In order to see how this can be useful, suppose that $\Pi = [c_1, c_2, ....., c_n, c_1]$ is a Jordan polygon and $f$ is the harmonic extension of the corresponding step function as

before, but now composed with a Möbius transformation so it is defined in $H$. Then, corresponding to (1.1) we have points

$$\zeta_1 < \zeta_2 < .. < \zeta_n$$

on the real axis,

$$f(x) = c_k \quad (\zeta_k < x < \zeta_{k+1}),$$

for $k = 1, ...., n-1$, and $f(x) = c_n$ for the interval $\{x < \zeta_1\} \cup \{x > \zeta_n\}$ containing infinity.

Let $\omega_k(z)$ be the harmonic measure of the interval $[\zeta_k, \zeta_{k+1}]$ with respect to $z$. The map $f$ can be expressed simply as a linear combination of the vertices $c_k$ weighted by the harmonic measure $\omega_k(z)$ of the interval that is mapped to $c_k$:

$$f(z) = c_1\omega_1(z) + c_2\omega_2(z) + .. + c_n\omega_n(z). \tag{3.1}$$

As noted in the introduction, if the map $f$ fails to be univalent, then there must be folding over the boundary, so it is natural to consider the local behavior of $f$ near an edge. Fix $m$ and let $z \to \zeta_m$. Then $f(z)$ approaches a value on the edge $[c_{m-1}, c_m]$. Applying the lemma, we obtain an approximation for $\omega_k(z)$ in terms of the lengths $\ell_j$ of the intervals $[\zeta_j, \zeta_{j+1}]$. Namely, when $m < k < n$,

$$\omega_k(z)/y \approx \frac{\ell_k}{(\ell_m + \ell_{m+1} + .. + \ell_{k-1})^2 + (\ell_m + \ell_{m+1} + .. + \ell_{k-1})\ell_k}.$$

We obtain a similar expression for $\omega_k(z)$ when $k < m$, and when $k = n$ (corresponding to the infinite interval) we have

$$\omega_n(z)/y \approx \frac{1}{\ell_m + \ell_{m+1} + .. + \ell_{n-1}}.$$

Guided by these approximations, one may quantify in terms of the relative lengths of the intervals, the contributions of the individual terms in (3.1). For the mapping problem of the current paper, one may choose the lengths $\ell_k$ in order to prevent folding near some edge $[c_{m-1}, c_m]$, and in order to simultaneously prevent folding over all edges, the lengths $\ell_k$ must satisfy a system of inequalities.
